

PRESENTER RUNBOOK • KEEP THIS ON THE SECOND SCREEN

Twenty minutes on Preckon

The pre-flight, the minute-by-minute, the five-minute demo click path, and the answers to the fourteen questions a CTO actually asks. Companion to the briefing deck.

AUDIENCE • ENTERPRISE / STRATEGIC PARTNER RUNTIME • 20:00 INCLUDING A LIVE DEMO

PREPARED 21 AUGUST 2026

T-60 **Nothing on this list is optional**

BEFORE
THE
ROOMPRE-
FLIGHT

A live demo inside a twenty-minute slot has no slack in it. Every item below has cost somebody a demo before.

The workspace

- ☐ Sign in to `app.preckon.com` and leave the session open.
Signing in on stage burns forty seconds and exposes the login rate limit.
- ☐ Open the finished demo project — *not* an empty one.
The project page only makes sense with work in it. Chain progress and the attention counts are the point.
- ☐ Confirm the BOQ has confirmed lines with traceable sources.
Beat 03 dies without this. Click one line through to its trace now, then back out.
- ☐ Verify the worker is up and the queue is empty.
A backlog from an earlier run makes your live run look slow.
- ☐ Run **Verify audit chain** once, privately, and confirm it returns clean.
You are going to press this in front of them. Never press it cold.
- ☐ Have a second confirmed artifact you are willing to *edit* live, to trigger the stale cascade.

The machine

- ☐ Browser zoom at 110–125%.
A BOQ table at 100% is unreadable from the far side of a boardroom.
- ☐ Close every other tab, notification, and chat client.
One Slack toast during the trace and the room is looking at that instead.
- ☐ Deck open in one window, workspace in another. Practise the switch.
Alt-tabbing through six windows on stage reads as unprepared.
- ☐ Phone tethering ready as a network fallback.
- ☐ A screen recording of the four demo beats, on the local disk, as the hard fallback.

The deck

- ☐ Press **T** to start the clock the moment you say your first word.
It goes amber when you are behind that slide's budget. Trust it.
- ☐ Fill the three blanks marked in **amber** below before you present.
- ☐ Read the **claims guardrail** section. Twice. It is the part that loses rooms.

00:00

TO

09:00

SLIDES

1-12

Nine minutes to earn the demo

This audience does not need the construction pain explained at length — they need to believe the architecture is real before they will read the demo as evidence rather than as a video. Move fast through the problem; slow down on governance.

CLOCK	SLIDES	BLOCK	THE ONE THING IT MUST LAND
00:00	1	Open	You will name what isn't finished. Said in the first sentence.
00:30	2–3	Problem & category	Every stage-tool hands off to a spreadsheet, and that's where the trail dies.
02:00	4–6	What it is	Every number can name its source. Say it, then two full seconds of silence.
03:50	7–9	Architecture	Two planes, a data-defined vertical, and an artifact that carries its own parentage.
06:50	10–12	Governance	The AI structurally cannot commit. Four syscalls, none of them writes state.
09:00	13	Hand to browser	Leave the demo slide up while you switch windows.

Where to spend, where to sprint

- **Sprint slide 5.** Do not read eight module names aloud. Name three, say the word "chain, not suite", move.
- **Spend on slide 10.** "Agents propose, humans dispose" is the slide that converts a risk-averse CTO. Every AI failure story they have read is a model taking an action. Tell them the failure mode here is a bad proposal a human rejects.
- **Spend on slide 11.** Frontier inference is the sixth thing tried, not the first. Thirty-four deterministic engines do the arithmetic. This is simultaneously the accuracy answer, the cost answer and the sovereignty answer — three objections retired by one diagram.
- **Sprint slide 12.** Twenty-five seconds. You are about to *show* the verify button; showing beats telling.

THE TRANSITION INTO THE DEMO

"That's the architecture. Now — none of it matters if the thing doesn't work, so let me show you the running system, and I'd like you to choose what we look at."

Handing them the choice before you open the browser is what separates a demo from a video. Do it in the sentence *before* you switch windows, not after.

09:00 TO **LIVE** **Four beats, five minutes, one click path**14:00 **DEMO**

Drive this in one direction. The single most common way a demo of this product fails is the presenter going back to show something they forgot.

BEAT 01 Propose

60 seconds · to 10:00

Projects > the live bid > project page > run a stage

"This is a real bid in a real tenant. Along the top is the lifecycle — documents, tender, drawings, specs, bill, estimate, programme, procurement, submission. That's a bid in the order you actually do it."

DO Point at *Needs your attention* and read one real count aloud. A number like "119 proposals" lands harder than any adjective.

"Nothing on this screen was committed by software. Every one of those is a proposal waiting on a person."

BEAT 02 Dispose

60 seconds · to 11:00

Review > inspect one > Confirm > reject another

"Agents propose, I dispose. Watch the pursuit state at the bottom — it just moved from Received to Qualifying. Not because someone dragged a card, but because I accepted the tender summary, and that *is* what qualifying means."

DO Reject one as well as confirming one. A demo where everything is accepted looks like a demo where nothing can be refused.

SAY ONCE Confirming is a permission. Every confirm lands on the audit chain against my name.

BEAT 03 Correct — the peak

120 seconds · to 13:00

B0Q > they pick a line > trace to source > edit it > stale ca

"Pick a line. Any line — I'd rather you chose than I did."

DO Genuinely let them choose. Then *stop talking* while they read the trace. This silence is the most persuasive fifteen seconds in the whole twenty minutes.

"That quantity came from that measurement, which came from that layer of that drawing. This is the question every estimator gets asked in a post-tender meeting, and it is normally answered from memory."

If a quantity looks wrong — and one might

NEVER DEFLECT. Say: "Good. That's exactly the case this is built for. Watch." Then correct it live.

"I just disagreed with the software. It kept its version, recorded mine against my name, and told me exactly what now needs re-running. That is the part estimating software has always been missing — not the correction. The *consequences* of the correction."

WHY A VISIBLE ERROR HELPS YOU HERE

A flawless demo of an AI product invites the thought that it was staged. A correction, handled without flinching, proves the review gate is load-bearing rather than decorative. If they find the error, you have won the slide.

BEAT 04 Verify

60 seconds · to 14:00

Trace > Verify audit chain > switch language to Arabic > switch

"Everything you have watched me do is on that chain. If a record had been altered behind the application's back, that check is where it would show. That is the difference between a log and evidence."

DO Switch the workspace to Arabic and leave it there for a beat before switching back. Say one line only: "Same workspace. Not a translated copy of it." For a GCC-facing partner this is worth more than a slide about localisation.

IF IT BREAKS

A slow run: stop, look at the room, say "that pause is it reading rather than guessing" — once — then wait. Do not apologise twice for the same pause.

A hang or an error: move to Trace on already-confirmed records. The provenance story does not need a live run to land, and beat 03 is the peak anyway.

Total loss of the workspace: go to the local recording, say "I'd rather show you the recording than watch a spinner with you", and keep the same four beats. Then offer a full live session as a follow-up — which is a better second meeting than you would otherwise have got.

14:00 TO 20:00 SLIDES 14-20 **Six minutes of honesty, then the ask**

This is the segment that distinguishes the briefing from a pitch. Do not rush it to make room for more demo — the demo has already done its work.

CLOCK	SLIDES	BLOCK	THE ONE THING IT MUST LAND
14:00	14-15	Build state	79% measured against the spec as written, not a roadmap we could move.
16:00	16	The gaps	You told them before they found it. Spend the full minute.
17:10	17-18	Deployment	Four shapes, one codebase. No rip and replace, ever.
18:30	19-20	Ask & close	One bid, one golden set, one security counterpart. Then stop talking.

Slide 16 is the whole reason this meeting works

Sixteen open POs, eight of which a CTO would find in a diligence pass. Naming them yourself converts the room's default posture from *auditing you* to *solving with you*. The distinction to draw out loud:

"Notice what these are and aren't. None of them is 'the chain doesn't work' or 'provenance is aspirational'. They're the operations layer — SSO, MFA, CI, staging, backups. Unglamorous, bounded, and exactly what gets fixed fast with a partner who has done it before."

The close

Do Say the final three lines slowly. Then stop. Do not add next steps, do not offer to send the deck, do not fill the silence. Let them ask the first question.

If the silence runs past ten seconds, the only acceptable line is: *"What would you want to test first?"* Anything else undoes the close.

— NON-NEGOTIABLE

GUARDRAIL

What is true, and what you must not say

This product's entire argument is that every number can name its source. The moment you overstate one thing, the room is entitled to doubt all of it — and with this audience, they will.

THE MARKETING SITE IS AHEAD OF THE BUILD ON THREE CLAIMS

The public security page currently presents **SSO, encryption at rest** and **row-level security** as live. None of the three is built. The deployed database is MySQL, which has no row-level security at all — tenant isolation is enforced in the repository layer instead, deliberately and with a test that asserts a cross-tenant read returns zero rows.

If anyone in the room has read that page, correct it yourself before they raise it. "Our marketing site is ahead of the build on three of those and we're fixing the copy." Getting caught on this costs you the room, and it is entirely avoidable.

CLAIM	REALITY	HOW TO SAY IT
Tamper-evident audit chain	BUILT	Show it. Press the verify button.
Tenant isolation	BUILT	Repository-layer, not Postgres RLS. Say which, unprompted.
Provenance on derived values	BUILT	Show it in beat 03.
AI governance: policy, registry, budgets, ledger	WIRED, REPORT-ONLY	"Consulted and recorded on every call. Enforcement is behind a flag."
Retrieval / RAG	DOCLOGIX ONLY	No embeddings generated yet. Do not imply semantic search across the platform.
SSO / MFA / encryption at rest	NOT BUILT	On slide 16, in your own words, before they ask.
Private / sovereign deployment	ARCHITECTURALLY SUPPORTED	"Supported by the architecture, not yet delivered in anger." Never imply a reference customer.
SOC 2	NOT HELD	Controls in progress. Never say "SOC 2 compliant".

Three things that are true, and worth volunteering

- **Two people cannot edit the same drawing at once.** Markup is per-person until saved; two people produce two revisions rather than one merged drawing.
- **The 3D view of a DXF assumes a storey height.** A DXF carries no heights. It is a sense-check, not a model. Say so before someone tests it.

- **It does not replace an estimator.** It does the reading and the arithmetic and shows its working. Somebody still has to decide.

THE SENTENCE THAT SAVES EVERY UNKNOWN

"Not today. Tell me what that would let you do and I'll find out where it sits."

That costs nothing in the room. Guessing costs the deal about a week after they sign.

Q&A

AFTER
THE
CLOSE

14

ANSWERS

What this audience actually asks

Ordered by how likely they are. The first five come up in almost every enterprise conversation.

01 "What happens when the AI is wrong?"

"A human rejects a proposal. That's the failure mode, and it's the only one available to it — the AI has four calls and none of them writes authoritative state. It can propose, read, queue a job, and ask for review. There is no fifth call."

Then add the correction story from beat 03: the disagreement is recorded against a name, and the downstream goes stale. Being wrong is a designed-for state, not an incident.

02 "Where does our data go? Which providers see it?"

"Deterministic software first, then cache, then retrieval, then a small private model, then a private reasoning model. A frontier provider is the sixth thing tried, and only when tenant policy permits it for that data classification. Policy overrides model quality — a restricted document does not leave its boundary because an external model happens to be better."

Add: model references in code are aliases, never vendor names. And every attempt is recorded with tenant, project, user, module, route and cost.

03 "Can we run this entirely inside our own environment?"

Yes architecturally — that is what shapes three and four on slide 17 are. Be precise about maturity: **SaaS and dedicated cloud are proven in the deployed system; private and sovereign are supported by the architecture and specified, not yet delivered to a customer.**

"The reason it isn't a rewrite is that no module ever calls a model directly. Everything goes through the fabric, and every model is an alias. Sovereign deployment is a routing configuration, not a fork."

04 "You don't have SSO. When?"

Do not invent a date. Turn it into the third ask.

"It's on the P0 list and it's a deal blocker — we know. That's precisely why ask number three is a named security counterpart on your side. We'd rather close SSO, MFA, CI, staging and backups *with* you during the pilot than have you wait six weeks and then start evaluating."

05 "Who else is running this?"

YOU MUST FILL THIS IN

I do not have your customer or pilot list. Write the honest answer here before you present: **named references, or "none yet"**. If it is none yet, say so plainly and immediately pivot to the golden-set ask — an early partner shapes the roadmap, and that is a genuine advantage, not a consolation.

06 "Isn't this just a wrapper around Claude?"

"Thirty-four deterministic engines do the arithmetic — CPM, measurement, BOQ reconciliation, revision diffing, clash. A model is used where reading unstructured documents genuinely requires one, and it is the sixth thing we try. If you swapped every model provider tomorrow, the bill still computes and the programme still solves."

Then the structural point: a wrapper cannot tell you what a number derived from. The artifact chain, the provenance record and the stale cascade are the product; the model is a component inside it.

07 "MySQL, not Postgres — why? What about row-level security?"

Answer it head on; a hedge here is worse than the fact.

"It's a deliberate divergence and it's documented. The design was written for Postgres row-level security. The deployment constraint chose MySQL, which has none — so isolation moved into the repository layer, behind a single enforced choke point, with a test that asserts a cross-tenant read returns zero rows. The other casualty is pgvector, which is why retrieval is currently narrower than the blueprint."

08 "What's your accuracy? What's the error rate on a takeoff?"

YOU MUST FILL THIS IN

I have no measured accuracy figures in the repository — only the accuracy *framework* (confidence thresholds, golden sets, tolerance tracking, correction-rate telemetry). **Do not quote a percentage you cannot source.**

"I'm not going to give you a number I can't defend, and that's exactly why ask number two is a golden set. Give us one design set paired with its final priced BOQ and accuracy stops being a claim on a slide — it becomes a regression fixture that either passes or doesn't, in front of you."

This answer is stronger than any percentage would have been. It converts a weakness into the ask.

09 "What does AI cost you per project? Does the margin work?"

"That's what the execution ladder is for. We don't monetise tokens — packaging is by projects, users, modules and deployment shape, so an efficiency gain improves our margin rather than cutting your price. And every attempt is attributed per tenant, project, user, module and route, so AI spend is a product KPI rather than an invoice surprise."

CAVEAT TO STATE IF PRESSED FOR A FIGURE

Cost reporting is currently built on under-counted data until the per-attempt ledger is fully populated. Say that rather than quoting a number.

10 "How do we get our data out?"

Ninety API routes, typed artifacts with JSON schemas, and exports at every stage — bill, estimate, programme, procurement package, plus full audit export. The domain model is documented rather than proprietary.

"Your data is yours, and the export isn't a retention feature we grudgingly added — it's how the modules talk to each other, so it has to be complete."

11 "How does this sit with our ERP, P6 and Autodesk?"

Phase A, coexist: import and export against the Autodesk ecosystem, IFC, DWG and DXF, PDF, Excel, P6 and ERP. Be honest about the sharpest gap: **P6 import, calendars and baselines — the migration-first part of the scheduling mission — is specified but not yet built.** The CPM engine underneath it is real.

12 "What's the team, and what's the bus factor?"**YOU MUST FILL THIS IN**

I have no team size or structure from the repository. Write it here honestly: **headcount, split, key-person risk**. If the team is small, say so — a partner-shaped conversation survives a small team; a discovered misrepresentation does not. The twelve ADRs and 13,074 lines of specification are your genuine evidence that the design is not held in one person's head.

13 "79% — what does the last 21% cost in time?"

Break it into two very different piles, because they are not the same kind of work.

- **Operations (SSO, MFA, CI, staging, backups, encryption at rest).** Known, bounded, unglamorous, and the fastest to close with a partner who has done it before. This is the pile that gates an enterprise deal.
- **Product depth (P6 migration, IFC and clash, recognition, post-award cost control, RFQ and commitments).** Genuine engineering, sequenced by which pilot needs it first — which is another reason to want a pilot.

"The honest version is that the second pile gets prioritised by whoever pilots first. That's not evasion — it's the reason we're asking for one live bid rather than a signature."

14 "Why won't Procore or Autodesk just build this?"

"They may. But they'd be building it downstream of where their data starts. Procore manages what you have already produced; Autodesk owns the model, not the bid. The hard part here isn't the AI — it's the chain from a raw tender document through to a defensible price, with provenance surviving every hop. That is a preconstruction problem, and preconstruction is the one stage neither of them started from."

Then the strategic point for a partner: *this is why the domain-neutral kernel matters*. The moat is not the construction pack — it is that the pack is data over a kernel that could carry another vertical.

± TIMING
RECOVERY

CUT
ORDER

If the clock goes against you**Running long — cut in this order**

- **Slide 18** (adoption phases). Fold it into one sentence on slide 17: "and nothing gets switched off in month one."
- **Slide 5** (the eight modules). The chain is already visible in the demo.
- **Slide 15** (evidence figures). Say only "every figure was queried this morning and we'll re-run any of them for you" and move on.
- **Beat 04 language switch.** Keep the verify button; drop the Arabic moment.

NEVER CUT THESE

Slide 6 (every number names its source), **slide 10** (agents propose, humans dispose), **beat 03** (trace and correct), **slide 16** (the gaps). Cutting slide 16 to save a minute converts an honest briefing into a pitch, and this audience can tell.

Running short — expand in this order

- **Beat 03.** Trace a second line, of a different type. Repetition is what makes provenance believable rather than a party trick.

- **Slide 8.** The four syscalls, and what an agent structurally cannot do. Technical audiences enjoy this and it costs you nothing in credibility.
 - **Slide 11.** Walk the ladder rung by rung with a real task at each level — document classification at the small model, requirement extraction at the reasoning model, ambiguous contract language at frontier.
 - **Slide 16.** Go through all sixteen POs rather than the eight. It is the single most trust-building thing available to you.
-

Companion to the Preckon Enterprise Briefing deck · press N in the deck for the same notes, slide by slide

Figures throughout are drawn from the module completion audit, the deployed production database and the repository, as of 21 August 2026.
